

Individualism and Innovation:

Unraveling Culture's Influence Across Time*

Rouzhi Liang[†]

Latest version available here

Abstract

This paper examines the impact of individualism on innovation and economic development over time. I begin by extending the cross-country literature, using the same time-invariant cultural measures but incorporating a longer time horizon and additional control variables. The estimated effects of individualism are inconsistent across specifications and time periods, particularly when I control for institutions. To address the limitations of time-invariant measures, I then turn to a within-U.S. analysis and construct time-varying, ancestry-based measures of individualism. This variation enables the use of fixed effects to capture local institutions and isolate the influence of culture. The results suggest that individualism either has a negative impact or no significant effect on innovation and economic development, in contrast to the prevailing findings in the existing literature.

Keywords: culture, innovation, economic development, economic growth

1 Introduction

It's commonly believed in the literature that individualism promotes innovation and economic development by increasing incentives for technological innovation (Gorodnichenko and Roland, 2011a,b). However, this conclusion requires further discussion, given two important concerns. First, it only focuses on a short time period with a fixed measure of individualism, ignoring the fact that the influence of individualism evolves over time as societies develop. Second, because the measures of individualism are fixed at the country level, it's hard to disentangle the effect of culture from that of formal institutions such as the patent law. In the empirical analysis, this prevents the use of country fixed effects. As a result, studies often use institutional indices to account for institutions, which may interact with cultural traits and generate biased estimation.

This paper reassesses the influence of individualism on innovation and economic development by addressing those concerns. I first extend the previous cross-country studies by using a longer time scope and a richer set of controls. To better isolate the effect of individualism from that of institutions, I also conduct a within-US analysis and construct a time-varying proxy for individualism based on ancestry composition. This within-country approach allows for variation in culture at the county-group level with a common national institutional background, enabling the inclusion of local fixed effects and helping to better distinguish cultural influences from that of institutions.

The results challenge the conventional view. In the cross-country regressions, the sign, significance, and magnitude of individualism's influence are highly sensitive to the specification, especially when institutional factors are considered. Moreover, the influence of individualism changes across different time periods. In the within-US analysis, where national institutions are fixed, and local institutions can be controlled using local fixed effects, individualism either has no significant effect on, or negatively affects, innovation and economic

development.

Understanding why the findings of this paper differ from the existing literature is important. This paper’s results suggest that individualism’s influence may depend on historical and institutional contexts rather than being constant and universal. In the cross-country analysis, individualism can be correlated with institutional features such as property rights and legal origins, which can influence economic performance by themselves. Moreover, if individualism level and the impact of individualism change over time, estimation based on time-invariant cultural indexes within a short time period may obscure important dynamics. From this perspective, the positive influence of individualism documented in the previous literature may partially reflect institutional effects and may not be robust over time.

This paper contributes to several strands of the literature. First, it contributes to the literature on culture and economic development by reassessing the role of individualism using new empirical strategies that address both time variation and institutional confounding. Second, it relates to the literature on subnational cultural variation and its impact, showing how within-country analysis can provide insights that are difficult to obtain from cross-country comparisons. Third, it contributes to the literature on immigration and local economic development by using ancestry composition to construct time-varying measures of individualism and study its economic influence.

The rest of the paper is structured as follows. In Section 2, I review related literature. In Section 3, I revisit the analysis exploring the impact of individualism on economic development, TFP, and innovation across countries with an extended time scope and more controls. In Section 4, I explain the analysis within the US. Section 5 concludes.

2 Related Literature

This paper relates to the broad literature on culture and economic development, which studies how cultural traits shape economic outcomes through both individual incentives and social interactions. A large body of work has examined how cultural values such as long-term orientation, religion, family ties, and trust influence economic behavior, including investment, innovation, and growth (Alesina and Giuliano, 2014; Andersen et al., 2017; Becker and Woessmann, 2009; Dohmen et al., 2015; Galor and Özak, 2016; Zak and Knack, 2001). Building on this literature, this paper focuses on individualism as a key cultural dimension and studies its role in innovation and economic development.

The most closely related papers are Gorodnichenko and Roland (2011b) and Gorodnichenko and Roland (2017), which document a positive influence of individualism on innovation and economic development in cross-country data. These studies highlight the importance of individualism relative to other cultural dimensions and provide evidence that more individualistic societies exhibit higher levels of innovation and a faster pace of long-run economic growth. Their empirical strategy relies on country-level, time-invariant measures of individualism and uses cross-country variation in the culture measure to identify the effect of individualism.

While this approach has generated influential results, it raises two important concerns. First, time-invariant measures of culture do not capture the possibility that individualism itself and its influence may evolve over time as societies develop. If the level and effect of individualism depend on technological progress or other social backgrounds, estimates based on time-invariant measures may fail to catch the dynamics. Second, because culture is measured at the country level and does not vary over time, country fixed effects cannot be included. This makes it difficult to disentangle the influence of culture from that of formal institutions, such as property rights or legal origins, which are often correlated with cultural

traits and may not be fully captured by institutional controls.

This paper contributes to this literature in two ways. First, it revisits the cross-country evidence using a longer time horizon and a richer set of controls, thereby reassessing the robustness of previous findings. Second, it complements the cross-country analysis with a within-U.S. design that exploits time-varying ancestry composition to construct local measures of individualism. This approach relates to the growing literature that uses ancestry-based variation to study the economic effects of persistent cultural traits brought by immigrants (Fulford et al., 2020). Because cultural values can be transmitted across generations (Giavazzi et al., 2019), ancestry composition provides a natural source of cultural variation within a common national institutional environment in the U.S., given its immigration history.

More broadly, the paper also relates to the literature on immigrants' influence on local economic development. Previous studies have shown that immigrants can affect economic outcomes through both skills and culture (Ottinger, 2020). By focusing on individualism as a specific cultural trait, this paper contributes to understanding which cultural dimensions matter for economic performance.

3 Cross-country Analysis

This section reassesses the influence of individualism on innovation and economic development across countries. The main goal of this section is to examine whether the influence of individualism remains robust to a longer period, additional controls, instrument variables, and different proxies. I show that the cross-country evidence is highly sensitive to specification and unstable across time, which motivates the within-U.S. analysis in the next section.

3.1 Data and Measurement

I begin with Hofstede’s index of individualism at the country-level, the standard measure used in the existing cross-country literature (Hofstede et al., 2005). Because this measure is contemporary and time-invariant, it raises two concerns. First, reverse causality may arise if economic development affects cultural values. Second, time-invariant measures make it difficult to distinguish the effect of culture from that of institutions in panel settings.

To address concerns about reverse causality, I also consider historical proxies and instruments for individualism based on pronoun-drop language structure (Davis and Abdurazokzoda, 2016; Kashima and Kashima, 1998) and historical disease prevalence (Murray and Schaller, 2010). These measures are predetermined before modern economic outcomes and are therefore less likely to be influenced by modern economic development.

At the same time, these historical variables may still be correlated with institutional characteristics, since both culture and institutions are shaped by historical factors. As a result, the IV and proxy specifications should be interpreted primarily as robustness checks rather than as providing clean identification of the causal effect of culture.

The dependent variables are log GDP per capita, total factor productivity (TFP), and log patents per capita. Following Gorodnichenko and Roland (2017), I use GDP per capita as a measure of economic development, TFP as a measure of productivity, and patents as a proxy for innovation. The control variables include geography, religion, legal origins, and property rights.

3.2 Empirical Strategy

3.2.1 Baseline Specifications

I first estimate standard cross-country panel regressions:

$$Y_{it} = \alpha_0 + \alpha_1 Idv_i + \boldsymbol{\alpha_2 X}_{it} + \gamma_t + \phi_{continent} + \omega_{t,continent} + \epsilon_{it}, \quad (1)$$

where Y_{it} denotes log GDP per capita, TFP, or log patents per capita for country i in year t , Idv_i is Hofstede’s individualism index, and $\mathbf{X}_{it}$ includes the control variables. The specification includes year fixed effects, continent fixed effects, and continent-by-year interactions.

I begin with baseline specifications and then progressively introduce additional controls. To assess robustness, I also estimate alternative specifications using instrumental variables and historical proxies for individualism. These exercises allow me to examine whether the cross-country influence is stable across different specifications and measurements.

3.3 Results

3.3.1 Economic Development

The positive cross-country influence of individualism on GDP per capita is not robust across specifications. In baseline OLS regressions, individualism has a positive effect on GDP. However, the magnitude declines substantially once additional controls, particularly institutional variables, are included.

When instruments are used, the impact of individualism starts to lose statistical significance. However, the coefficient increases when geographic factors, religions, and property rights are considered. On the other hand, when the pronoun drop is used as a proxy, in-

dividualism's influence is not significant once legal origins are controlled. In other cases, the magnitude of individualism's influence drops. However, when religions are controlled, the impact of individualism increases. These patterns suggest that the relationship between individualism and economic development is unstable, especially when institutional factors are taken into account.

Note: Standard errors are clustered at the country and year level.

3.3.2 Total Factor Productivity

The results for total factor productivity show a similar lack of consistency and robustness. While individualism is positively associated with TFP in OLS regressions, the effect weakens or disappears once additional controls are introduced. The IV and proxy estimates are generally insignificant. Overall, the evidence does not support a stable relationship between individualism and productivity across countries.

Observations	3958	3958	3958	3958	3958	3958

Note: Standard errors are clustered at the country and year level.

3.3.3 Innovation

The results for innovation are likewise unstable. Individualism is positively correlated with patenting activity in baseline OLS regressions, but the magnitude declines once controls are included, except when controlling for legal origins. The IV and proxy estimates are not robust across specifications, and the impact of individualism only increases and stays significant when geographic characteristics are included in the IV regression. These findings suggest that the cross-country evidence does not show a stable relationship between individualism and innovation.

3.4 Additional Evidence

To further assess the robustness of the relationship, I present additional descriptive evidence in this section.

First, Figure 1 shows binned scatter plots with and without controls. The positive association between individualism and economic development becomes substantially flatter once controls are included, showing the sensitivity of the results to different specifications.

Figure 1: Binsreg Regression for economic development across countries

Second, I examine whether the relationship varies over time by including fixed effects for the interaction between individualism and year. Figure 2 shows that the association

between individualism and economic development is not stable over time. In earlier periods, countries with intermediate levels of individualism exhibit higher income levels, whereas in later periods, more individualistic countries perform better. This time variation further weakens the interpretation of a stable cross-country influence of individualism.

Results for total factor productivity and patenting activity can be found in the appendix.

Figure 2: Individualism's impact on economic development across time

3.5 Summary

The cross-country analysis does not provide robust evidence that individualism promotes economic development, productivity, or innovation. Across all outcomes, the estimated relationship is highly sensitive to controls, especially institutional controls, as well as to instruments, proxies, and time periods. These findings suggest that cross-country regressions based on static cultural measures cannot disentangle culture's influence from that of institutions. This motivates the within-U.S. analysis in the next section, where time-varying cultural measurement and local fixed effects enable cleaner identification of the role of individualism.

4 Within-U.S. Analysis

This section reassesses the relationship between individualism and economic outcomes within the United States. The within-country setting provides a useful environment because cultural variation can be studied under a common national institutional context. In addition, the

availability of time-varying local measures of individualism enables the inclusion of fixed effects, which helps address concerns about omitted-variable bias that arise in cross-country analyses.

The goal of this section is to examine whether the positive relationship between individualism and economic development documented in the cross-country literature remains robust once institutional differences are better controlled for and cultural variation is measured over time within a single country.

Following Fulford et al. (2020), I use the county group as the geographical unit of study since the Census reports data only at this level starting in 1950.

4.1 Measurement of Local Individualism

To construct a time-varying measure of individualism within the United States, I combine country-level individualism indices with county-group ancestry composition. The idea is that ancestry composition captures the cultural traits brought by immigrants and allows for variation of individualism across locations and over time.

Formally, individualism in the county group j at time t is defined as a weighted average of the individualism score at country i :

$$\text{Individualism}_{jt} = \sum_i \text{Ancestry Ratio}_{ijt} \times \text{Individualism}_i. \quad (2)$$

This measure varies across county groups because ancestry composition differs across locations, and evolves over time as ancestry shares change. Compared with standard cross-country measures of culture, this time variation makes it possible to include county-group or state fixed effects, which helps control for unobserved local characteristics and institutional factors.

4.2 Empirical Strategy and Instruments

I use panel regressions to study how the ancestry-weighted individualism measures impact local economic outcomes while controlling for fixed effects and population density. The main concern is that ancestry composition may be correlated with local economic performance or regional characteristics. In addition, the country-level individualism measures used to construct the index may themselves relate to ancestry composition.

To address these concerns, I apply instrumental variables that consider exogenous variation in both ancestry composition and country-level individualism. For ancestry shares, I use instruments based on historical settlement patterns and transportation networks from Fulford et al. (2020). For the country-level individualism component, I use historical measures such as language characteristics related to pronoun drop and historical disease prevalence, following the cross-country literature.

4.3 Linear Regression Results

4.3.1 Economic Development

Table 4 reports the results for log GDP per capita. Overall, the within-U.S. evidence does not support a positive influence of individualism on economic development.

In the baseline specifications with county group fixed effects, the estimated effect of individualism is insignificant but becomes negative once instrument variables for transportation are included. I also consider specifications with only state fixed effects. When state fixed effects are used instead, the estimates of individualism’s impact become more consistently negative. Across specifications, the results suggest that higher levels of individualism are not associated with higher economic development in the United States and may even be negatively associated with economic development.

Note: For OLS with county-group FE, standard errors are clustered at the county-group level. For other specifications, standard errors are clustered at the county group and year level.

4.3.2 Innovation

Table 5 presents the results for patenting activity. The pattern is consistent with the findings for GDP per capita.

In specifications with county-group fixed effects, the estimated relationship between individualism and innovation is generally insignificant and negative. When state fixed effects are used, the estimated coefficients become more consistently negative.

Overall, these results suggest that, within the United States, individualism does not robustly promote innovation and may be associated with lower levels of patenting activity.

4.4 Nonlinearity and the Distribution of Individualism

I next examine whether the relationship between individualism and economic outcomes is nonlinear.

4.4.1 Economic Development

Quadratic regressions show that the relationship between individualism and GDP per capita follows an inverted-U pattern, with positive effects at low levels of individualism and negative effects at higher levels. However, these patterns are not robust across all specifications, particularly in the IV regressions with state fixed effects, except when using the instrument

of ancestry stock.

To help interpret the difference between the linear and quadratic specifications, Figure 3 plots the fitted relationship between individualism and GDP per capita together with the distribution of county-group individualism. The figure shows that most county groups are concentrated in the upper range of the individualism distribution. Within this region, the fitted relationship is downward sloping. As a result, linear specifications primarily capture the average slope over the high-individualism region, which helps explain why the linear regressions yield negative coefficients even when the quadratic specification suggests a hump-

Figure 3: Individualism's impact on economic development within the US

shaped relationship.

4.4.2 Innovation

The results for patenting activity show a similar pattern. While some quadratic specifications suggest a hump-shaped relationship, the estimates are unstable across specifications and lose significance in most IV regressions.

Figure 4 provides further insight by plotting the fitted relationship between individualism and patenting alongside the distribution of individualism. Similar to the case of GDP, most county groups are located in the higher range of the individualism distribution, where the fitted relationship between individualism and innovation is downward sloping. This pattern helps explain why the linear specifications tend to produce negative estimates for innovation, despite some evidence of nonlinearity in the quadratic regressions.

4.5 Time Variation

4.5.1 Economic Development

I next examine whether the relationship between individualism and economic development varies over time. The results indicate substantial time variation. In earlier periods, lower levels of individualism are associated with higher economic performance, while in later peri-

Figure 4: Individualism's impact on patents within the US

ods, higher individualism tends to be associated with better outcomes. This pattern suggests that the effect of individualism is not stable over time.

Figure 5: Individualism's Influence on Economic Development within the US over time

4.5.2 Innovation

A similar pattern of time variation is observed for innovation. The relationship between individualism and patenting varies across periods, with no consistently positive or negative association. These results further support the view that the impact of individualism is not constant.

Figure 6: Individualism's Influence on Patents within the US over time

Additional figures and robustness checks, including results with fixed individualism categories, are reported in the appendix.

5 Conclusion

This paper reassesses the impact of individualism on innovation and economic development both across countries and within the US. I begin by revisiting the cross-country evidence that has been interpreted as supporting a positive role for individualism. Extending the analysis over a longer period and introducing richer controls, I show that the estimated relationship is highly sensitive to specification and unstable across time. These patterns

suggest that cross-country estimates based on time-invariant cultural measures are difficult to interpret, particularly because they may confound culture with institutions and other omitted variables.

I then turn to a within-U.S. analysis that constructs time-varying ancestry-weighted measures of individualism across county groups. This design allows the inclusion of local fixed effects and provides a setting for studying cultural variation within a common national institutional environment. The within-U.S. results do not support the positive relationship suggested by the cross-country literature. For both economic development and innovation, the estimated effect of individualism is either negative or statistically insignificant once local fixed effects are accounted for and instruments are used. Additional evidence of nonlinearity and time variation further suggests that the impact of individualism is unstable and cannot be characterized as universally positive.

These findings should be interpreted with appropriate caution. Although the within-U.S. analysis helps address some of the limitations of the cross-country approach, the results may still be specific to the U.S. setting. In particular, the effect of individualism may depend on the institutional and social environment. One possible interpretation is that in a highly individualistic society such as the United States, additional individualism may weaken cooperation rather than strengthen innovation and economic performance. Whether similar patterns arise in other countries remains an open question.

More broadly, the results suggest that the economic effects of culture are likely to be context-dependent rather than universal. Future research could extend this analysis to other countries with time-varying measures of culture and examine how cultural traits interact with institutions and other features of the social environment. In addition, this paper focuses on the quantity of innovation rather than its quality. Studying how individualism affects the quality of innovation would provide a more comprehensive understanding of culture's role in technological progress and economic development.

Appendix

A Additional Cross-country Results

This section reports additional country-level results not shown in the main text. For each outcome, I present alternative IV and proxy specifications using historical measures of individualism based on pronoun-drop language characteristics and historical disease prevalence. Across these alternative specifications, the estimated relationship between individualism and economic outcomes remains sensitive to controls, instruments, and measurement .

A.1 Log GDP per capita

Table A1 shows the regression results for individualism’s impact on economic development across countries using the pronoun drop from Kashima and Kashima (1998) as the instrument or proxy. The results in Panel A are the same as those in the paper, and I put them here just for reference. When I use the pronoun drop as the instrument, we notice that the coefficient drops when we include legal origins and property rights. When we consider geographic variables and religions, the coefficient increases. These inconsistent results indicate that individualism could correlate with different controls, leading to biased results in the country-level analysis. In Panel C, when we use the pronoun drop as the proxy, we see similar results as those in Panel B.

Table A2 and Table A3 show individualism’s influence on economic development across countries using the indexes of 9 and 7 historical diseases, respectively. In Table A2, the IV regression results show that the influence of individualism vanishes or drops when we

Note: Standard errors are clustered at the country and year level.

A.2 Total Factor Productivity

Table A4 indicates the regression results based on the pronoun drop from Kashima and Kashima (1998) for TFP. When I use the pronoun drop as the instrument, the significance of the coefficients disappears for most of the controls, except for religions. When we use the pronoun drop as the proxy instead, we only get significance when we consider legal origins.

Note: Standard errors are clustered at the country and year level.

Table A5 lists the regression results for TFP using the index of 9 historical diseases as the instrument and the proxy. The magnitude or significance of coefficients in both panels drops, except for the case when considering legal origins. This indicates that individualism might be highly correlated with legal origins. Similarly, Table A6 shows the influence of individualism on TFP when we use the index of 7 historical diseases as the instrument and the proxy. We notice the same pattern for those in Table A5 .

A.4 Additional Figures

Figures 7 and Figure 9 present additional binned scatter plots for TFP and patents. The relationship between individualism and TFP becomes a U-shape once controls are included. The results for patents are similar to those for log GDP per capita and become flatter when I consider control variables.

Figure 8 and Figure 10 show the result of time-varying estimates for TFP and patents.

Note: Standard errors are clustered at the country and year level.

It has been shown that individualism's influence is not time-consistent.

B Additional Within-U.S. Results

This section reports supplementary results for the within-U.S. analysis. I first present alternative instrumental variable specifications, then report additional evidence on nonlinearity, and finally provide supplementary figures that examine time variation using fixed individu-

B.1 Alternative IV Specifications

B.1.1 Economic Development

Table A10 reports the results for log GDP per capita using alternative instruments based on the pronoun-drop measure from Kashima and Kashima (1998) and the index of seven historical diseases from Murray and Schaller (2010).

Figure 7: Binsreg Regression for TFP across countries

Figure 8: Individualism's impact on TFP across time

Figure 9: Binsreg Regression for patents across countries

Figure 10: Individualism's impact on patents across time

The overall pattern is consistent with the main results. When county-group fixed effects are included, the estimated effect of individualism is generally statistically insignificant in OLS and in the ancestry-stock IV specification, but becomes negative and significant when using transportation-based instruments. When state fixed effects are included instead, the estimated influence is consistently negative across specifications.

B.1.2 Innovation

Table A11 presents the corresponding results for patenting activity. The findings are similar to those for economic development. Across specifications, individualism has either a negative or statistically insignificant effect on innovation.

Table A10: Individualism and Log GDP per capita within the US

	Log GDP per capita (1850-2010)

1st Stage F			6354.07	370.27	290.62	758.36
Observations	17631	17631	17631	17631	17631	17631

Note: For OLS with county-group FE, standard errors are clustered at the county-group level. For other specifications, standard errors are clustered at the county group and year level.

B.2 Additional Evidence on Nonlinearity

B.2.1 Economic Development

Table A12 reports quadratic specifications for log GDP per capita using the alternative instruments. The results are broadly consistent with those in the paper. Some specifications suggest an inverted-U relationship between individualism and economic development, with positive effects at lower levels of individualism and negative effects at higher levels. However, this nonlinear pattern is not stable across all IV specifications.

Table A11: Individualism and Log Patent per capita within the US

	Log Patent per 1000 people (1850-2010)					
	OLS		IV: Stock	IV: Trans.	IV: Trans. $\times$ KK	IV: Trans. $\times$ IHD7

Observations	12591	12591	12591	12591	12591	12591

Note: For OLS with county-group FE, standard errors are clustered at the county-group level. For other specifications, standard errors are clustered at the county group and year level.

B.2.2 Innovation

Table A13 reports quadratic specifications for patenting. Compared with economic development, the evidence of nonlinearity is weaker and less consistent. While some specifications suggest nonlinear patterns, the estimates are sensitive to the choice of instrument. Overall, the results do not provide robust evidence of a stable nonlinear relationship between individualism and innovation.

Table A12: Individualism and Log GDP per capita within the US

the high individualism group is catching up in economic development and eventually becomes the group with the highest log GDP per capita, even though it exhibited the lowest level of log GDP per capita in the beginning.

Figure 11: Individualism’s Influence on Economic Development within the US over time (Category Fixed at 1900)

B.3.2 Innovation

Figure 12 presents the results for patenting activity. The low individualism group exhibited a higher increase in innovation before 1930. After 1930, the high individualism group caught up with a higher increasing rate but fell after 2000.

Figure 12: Individualism’s Influence on Patents within the US over time (Category fixed at 1900)
